ON CHARACTERIZATIONS AND INTEGRALS OF GENERALIZED NUMERICAL RANGES

by

Moshe Goldberg and E. G. Straus*

Department of Mathematics ✓

University of California, Los Angeles

ABSTRACT. Let $c = (\gamma_1, \dots, \gamma_n)$ be given. The generalized numerical range of an $n \times n$ matrix A , associated with c , is the set $W_c(A) = \{\sum \gamma_j (Ax_j, x_j)\}$ where (x_1, \dots, x_n) varies over orthonormal systems in \mathbb{C}^n . Characterizations of this range, for real c , are given. Next, we study integrals of the form $\int W_c(A) d\mu(c)$ where $\mu(c)$ is a measure defined on a domain in \mathbb{R}^n . The above characterizations are used to study the inclusion relation $\int W_c(A) d\mu(c) \subset \lambda W_{c'}(A)$. We determine those λ , for which this inclusion holds for all $n \times n$ matrices A . Such relations lead to more elementary ones, when the integral reduces to a finite linear combination of ranges. In particular, we obtain the inclusion relations of the form $W_c(A) \subset \lambda W_{c'}(A)$ which hold for all A .

Finally, using the above characterization of W_c , we investigate inclusion relations of the form

$$(1.2) \quad \int_{\mathfrak{A}} W_c(A) d\mu(c) \subset \lambda W_{c'}(A), \quad \lambda = \text{constant},$$

which hold, uniformly, for all $A \in C_{n \times n}$, i.e., for all n -square matrices. If the measure $\mu(c)$ is concentrated on a finite number of vectors c , then (1.2) is reduced to inclusion relations involving finite linear combinations of generalized numerical ranges. Such relations were considered in earlier works [2, 3].

In particular, for given vectors c, c' we obtain necessary and sufficient conditions under which

$$W_c(A) \subset \lambda W_{c'}(A), \quad \forall A \in C_{n \times n}.$$

2. Characterization of generalized ranges. For any vector $c = (\gamma_1, \dots, \gamma_n)$ consider the diagonal matrix

$$C = \text{diag}(c) = \text{diag}(\gamma_1, \dots, \gamma_n),$$

and construct the class of matrices

$$U_c = \text{conv}\{UCU^* : U \text{ unitary}\},$$

where conv denotes the convex hull.

Since we restrict attention to $c \in \mathbb{R}^n$ it is evident that the elements of U_c are Hermitian.

Using U_c we have the following characterization of ranges with real coefficients.

THEOREM 1. If $c \in \mathbb{R}^n$ then

$$W_c(A) = \{\text{tr}(HA) : H \in \mathcal{U}_c\} .$$

Proof. It follows from the definition of $W_c(A)$ in (1.1) that

$$W_c(A) = \{\text{tr}(CU^*AU) : U \text{ unitary}\} .$$

Thus

$$(2.1) \quad W_c(A) = \{\text{tr}((UCU^*)A) : U \text{ unitary}\} ,$$

which implies that

$$W_c(A) \subset \{\text{tr}(HA) : H \in \mathcal{U}_c\} .$$

For the converse inclusion let

$$H = \sum_i \lambda_i (U_i C U_i^*) ; \quad \lambda_i \geq 0 , \quad \sum_i \lambda_i = 1 ,$$

be an arbitrary element of \mathcal{U}_c . By the convexity of W_c and by (2.1) we have

$$\text{tr}(HA) = \sum \lambda_i \text{tr}((U_i C U_i^*)A) \in W_c(A) .$$

So,

$$\{\text{tr}(HA) : H \in \mathcal{U}_c\} \subset W_c(A) ,$$

and the theorem follows.

We introduce two definitions which lead to another characterization of $W_c(A)$.

DEFINITION 1. (i) A real vector $c = (\gamma_1, \dots, \gamma_n)$ is called ordered if

$$\gamma_1 \geq \gamma_2 \geq \dots \geq \gamma_n .$$

(ii) We say that c, c' satisfy $c' < c$ if there exists a doubly stochastic matrix S (i.e., a matrix with nonnegative entries whose row sums and columns sums equal 1), such that $c' = Sc$.

In Theorem 7 of [3] we proved the following.

LEMMA 1. For ordered c, c' we have $c' < c$ if and only if

$$\sum_{j=1}^{\ell} \gamma'_j \leq \sum_{j=1}^{\ell} \gamma_j, \quad \ell = 1, \dots, n,$$

with equality for $\ell = n$.

DEFINITION 2. Let $c \in \mathbb{R}^n$, and let Λ_{ℓ} ($1 \leq \ell \leq n$) be the set of all orthonormal ℓ -tuples of vectors in \mathbb{C}^n . We define \mathcal{H}_c to be the class of all Hermitian matrices H for which

$$(2.2) \quad \sum_{j=1}^{\ell} (Hx_j, x_j) \leq \sum_{j=1}^{\ell} \gamma_j, \quad \forall (x_1, \dots, x_{\ell}) \in \Lambda_{\ell}, \quad \ell = 1, \dots, n,$$

with equality for $\ell = n$.

Let e_1, \dots, e_n be the standard basis of \mathbb{C}^n . Note that if $\sum \gamma_j = 0$ (which is the case assumed in Section 3), then the equality for $\ell = n$ in 2.2 implies that

$$\sum_{j=1}^n (He_j, e_j) = \sum \gamma_j = 0;$$

i.e., all members of \mathcal{H}_c have trace 0.

LEMMA 2. If c is ordered then $\mathcal{H}_c = \mathcal{H}_c$.

Proof. Take a unitary matrix and orthonormal vectors x_1, \dots, x_{ℓ} , ($1 \leq \ell \leq n$). Since the vectors $y_j = U^* x_j$, $j = 1, \dots, \ell$, are orthonormal as well, it is not hard to verify that

$$(2.3) \quad \sum_{j=1}^{\ell} (UCU^* x_j, x_j) = \sum_{j=1}^{\ell} (Cy_j, y_j) \leq \gamma_1 + \dots + \gamma_{\ell}, \quad c = \text{diag}(c),$$

with equality for $\ell = n$. Therefore, if

$$H = \sum_i \lambda_i U_i C U_i^*, \quad \left(\lambda_i \geq 0, \sum_i \lambda_i = 1 \right),$$

is any (Hermitian) matrix in \mathcal{U}_C , we find by (2.3) that

$$\sum_{j=1}^{\ell} (H x_j, x_j) = \sum_{j=1}^{\ell} \sum_i \lambda_i (U_i C U_i^* x_j, x_j) \leq \sum_i \lambda_i \sum_{j=1}^{\ell} \gamma_j = \sum_{j=1}^{\ell} \gamma_j,$$

with equality for $\ell = n$. So, by Definition 2, $H \in \mathcal{H}_C$, and consequently

$$\mathcal{U}_C \subset \mathcal{H}_C.$$

Conversely, take any $H \in \mathcal{H}_C$. Since H is Hermitian, it is unitarily similar to a real diagonal matrix, i.e., there exists a unitary V such that

$$(2.4) \quad C' \equiv V^* H V = \text{diag}(\gamma'_1, \dots, \gamma'_n),$$

where we may assume that $c' = (\gamma'_1, \dots, \gamma'_n)$ is ordered. Using

(2.2) and the orthonormal vectors $x_j = V e_j$, $j = 1, \dots, \ell$, we find that

$$\sum_{j=1}^{\ell} \gamma'_j = \sum_{j=1}^{\ell} (C' e_j, e_j) = \sum_{j=1}^{\ell} (V^* H V e_j, e_j) = \sum_{j=1}^{\ell} (H x_j, x_j) \leq \sum_{j=1}^{\ell} \gamma_j,$$

with equality for $\ell = n$. That is, by Lemma 1, $c' < c$. Hence, there exists a doubly stochastic matrix S such that $c' = S c$. Now recall that doubly stochastic matrices are convex combinations of permutation matrices P_{σ} . In particular $S = \sum_{\sigma \in S_n} \lambda_{\sigma} P_{\sigma}$. Thus

$$(2.5) \quad c' = \sum_{\sigma \in S_n} \lambda_{\sigma} P_{\sigma} c; \quad \lambda_{\sigma} \geq 0, \quad \sum \lambda_{\sigma} = 1,$$

where S_n is the symmetric group. Since for every B , $P_{\sigma} B P_{\sigma}^*$ has both the rows and columns of B permuted according to σ , we have

$$(2.6) \quad \text{diag}(P_{\sigma} c) = P_{\sigma} \text{diag}(c) P_{\sigma}^* = P_{\sigma} C P_{\sigma}^*.$$

So, by (2.5), (2.6),

$$(2.7) \quad c' = \text{diag}(c') = \sum_{\sigma} \lambda_{\sigma} \text{diag}(P_{\sigma} c) = \sum_{\sigma} \lambda_{\sigma} P_{\sigma} C P_{\sigma}^* .$$

From (2.4) and (2.7) we obtain

$$(2.8) \quad H = VC'V^* = \sum_{\sigma} \lambda_{\sigma} [(VP_{\sigma}) C (VP_{\sigma})^*] = \sum_{\sigma} \lambda_{\sigma} (U_{\sigma} C U_{\sigma}^*) , \quad \lambda_{\sigma} \geq 0 , \quad \sum \lambda_{\sigma} = 1 ,$$

where $U_{\sigma} \equiv VP_{\sigma}$ are, of course, unitary. Hence, $H \in \mathcal{U}_c$, i.e., $\mathcal{H}_c \subset \mathcal{U}_c$ and the proof is complete.

Theorem 1 together with Lemma 2 imply a second characterization of generalized numerical ranges with real coefficients.

THEOREM 2. If c is ordered then

$$W_c(A) = \{\text{tr}(HA) : H \in \mathcal{H}_c\} .$$

Another simple consequence of the last lemma and the convexity of \mathcal{U}_c is that for ordered c , \mathcal{H}_c is convex.

At this point we recall the definition of the k -numerical range, ($1 \leq k \leq n$), given by Halmos [4, §167], which after a convenient normalization becomes

$$W_k(A) = \left\{ \frac{1}{k} \text{tr}(PAP) : P = \text{orthogonal projection of rank } k \right\} .$$

It can be verified that $W_k(A)$ may be written as

$$W_k(A) = \left\{ \frac{1}{k} \sum_{j=1}^k (Ax_j, x_j) : (x_1, \dots, x_k) \in \Lambda_k \right\} .$$

Hence we see that

$$W_k(A) = W_{c_k}(A) , \quad \text{with } c_k = \frac{1}{k} (e_1 + \dots + e_k) .$$

That is, the k -numerical range is a special case of the generalized numerical range.

The matrices M_{c_k} are those Hermitian matrices which satisfy Definition 2 with $c = c_k$. Using this definition one can show that

$$M_{c_k} = \{\text{Hermitian } H : 0 \leq H \leq \frac{1}{k} I, \text{ tr}(H) = 1\}.$$

Thus Theorem 2 generalizes the result

$$W_k(A) = \{\text{tr}(HA) : 0 \leq H \leq \frac{1}{k} I, \text{ tr}(H) = 1\}, \quad k = 1, \dots, n,$$

of Fillmore and Williams [4, Theorem 1.2].

3. Integrals of generalized ranges. In this section we are interested in linear combinations, or more generally, in integrals of the sets $W_c(A)$, where A is arbitrary but fixed, and c varies in some domain of \mathbb{R}^n .

Let $c = (\gamma_1, \dots, \gamma_n)$ be a real vector with $\gamma \equiv \sum \gamma_j \neq 0$, and consider the vector $b = (\beta_1, \dots, \beta_n)$ defined by

$$b = c - \left(\frac{\gamma}{n}, \dots, \frac{\gamma}{n}\right).$$

We have $\sum \beta_j = 0$ and

$$B \equiv \text{diag}(b) = \text{diag}(c) - \frac{\gamma}{n} I = C - \frac{\gamma}{n} I.$$

So, by Theorem 1,

$$W_b(A) = \{\text{tr}(UBU^*A) : U \text{ unitary}\}$$

$$= \{\text{tr}[U(C - \frac{\gamma}{n} I)U^*A] : U \text{ unitary}\} = W_c(A) - \left\{\frac{\gamma}{n} \text{tr}(A)\right\}.$$

This argument suggests that it is convenient to restrict attention to those vectors c for which $\sum \gamma_j = 0$. The limitation merely involves a translation of the ranges by multiples of the trace, or, equivalently, the restriction to matrices of trace 0.

Since W_c is invariant under permutations of the γ_j , we may assume that each vector c in our domain is ordered. Hence, we consider the set of ordered vectors c with $\sum \gamma_j = 0$, which form a conical subset C of an $(n-1)$ -dimensional subspace of \mathbb{R}^n .

We are ready now to study integrals of $W_c(A)$ relative to an arbitrary measure μ on C , that is integrals of the form

$$(3.1) \quad J_\mu = J_\mu(A) = \int_C W_c(A) d\mu(c).$$

One way of defining the integral in (3.1) is by carrying linear sums, over partitions of C , to the limit. Alternatively, one realizes that J_μ , being an integral of the convex sets W_c , is a convex set as well. Hence J_μ may be characterized by its support function (e.g. [2] part V),

$$u(J_\mu, \theta) = \sup_{z \in J_\mu} \operatorname{Re}(ze^{-i\theta}), \quad 0 \leq \theta < \pi$$

In order to evaluate $u(J_\mu, \theta)$, we consider the support functions of our closed convex integrands W_c . We have

$$u(W_c, \theta) = u(c, \theta) = \max_{z \in W_c} \operatorname{Re}(ze^{-i\theta}), \quad 0 \leq \theta < \pi$$

Since $u(c, \theta)$ is a linear function of c in the sense that

$$u(\lambda W_c + \lambda' W_{c'}, \theta) = \lambda u(c, \theta) + \lambda' u(c', \theta), \quad \forall \lambda, \lambda' \geq 0,$$

we have

$$u(J_\mu, \theta) = u\left(\int W_c d\mu(c), \theta\right) = \int u(W_c, \theta) d\mu(c) = \int u(c, \theta) d\mu(c)$$

Of course, the measure μ may be concentrated at a finite number of points $c_1, \dots, c_m \in C$. In this case the integral J_μ reduces to the finite linear combination

$$\mu(c_1)W_{c_1}(A) + \dots + \mu(c_m)W_{c_m}(A) .$$

Since $W_{\lambda c} = \lambda W_c$ for scalar λ , we shall avoid integration over proportional vectors of C . This can be achieved by restricting integration to the domain

$$\mathfrak{N} = \{c : c = (\gamma_1, \dots, \gamma_n), \sum \gamma_j = 0, \gamma_1 = 1\} ,$$

which is the bounded set of all vectors in C with $\gamma_1 = 1$.

The above concept of integration can be extended in order to consider the integral

$$(3.2) \quad \mathfrak{H}_\mu \equiv \int_{\mathfrak{N}} \mathfrak{H}_c d\mu(c) .$$

We recall that the integrands \mathfrak{H}_c are convex sets in the $(n^2 + n - 2)$ real dimensional space \underline{H} of Hermitian matrices of trace 0. It follows that \mathfrak{H}_μ is also a convex set in \underline{H} . Again, the convexity of \mathfrak{H}_c and \mathfrak{H}_μ implies that the integral may be defined in terms of the support functions of \mathfrak{H}_c . Here, in analogy to the previous case, the support function of \mathfrak{H}_c assigns to each point H_1 on the unit sphere of \underline{H} , the distance from the origin O of \underline{H} to the plane of support of \mathfrak{H}_c perpendicular to the direction $\overrightarrow{OH_1}$.

Having the integrals J_μ and \mathfrak{H}_μ defined we state our main result.

THEOREM 3. Let μ be a nonnegative measure on \mathfrak{A} , and let $c' \neq 0$ be an ordered vector with $\sum \gamma_j' = 0$. Then

$$(3.3) \quad \int_{\mathfrak{A}} W_c(A) d\mu(c) \subset \lambda W_{c'}(A), \quad \forall A \in \mathbb{C}_{n \times n},$$

if and only if $\lambda \geq \eta(c')$ or $\lambda \leq \zeta(c')$ where

$$(3.4a) \quad \eta(c') = \max_{1 \leq \ell < n} \int_{\mathfrak{A}} \frac{\gamma_1 + \dots + \gamma_{\ell}}{\gamma_1' + \dots + \gamma_{\ell}'} d\mu(c),$$

$$(3.4b) \quad \zeta(c') = \min_{1 \leq \ell < n} \int_{\mathfrak{A}} \frac{\gamma_1 + \dots + \gamma_{\ell}}{\gamma_n' + \dots + \gamma_{n-\ell+1}'} d\mu(c).$$

Proof. In the proof of Lemma 7 of [3] we have shown that if $c' \neq 0$ with $\sum \gamma_j' = 0$, then

$$(3.5) \quad \gamma_1' + \dots + \gamma_{\ell}' > 0, \quad \gamma_n' + \dots + \gamma_{n-\ell+1}' < 0; \quad \ell = 1, \dots, n-1.$$

This establishes that η, ζ of (3.4) are well defined and since μ is a nonnegative measure we see that $\eta \geq 0, \zeta \leq 0$.

Next we show that $\lambda \geq \eta(c')$ or $\lambda \leq \zeta(c')$ imply (3.3). For this purpose we use the definition of \mathfrak{H}_{μ} , Theorem 2, and the linearity of the trace to evaluate the set on the left of (3.3):

$$(3.6) \quad \begin{aligned} \int_{\mathfrak{A}} W_c(A) d\mu(c) &= \int_{\mathfrak{A}} \{\text{tr}(HA) : H \in \mathfrak{H}_c\} d\mu(c) \\ &= \left\{ \text{tr}(HA) : H \in \int_{\mathfrak{A}} \mathfrak{H}_c d\mu(c) \right\} = \{\text{tr}(HA) : H \in \mathfrak{H}_{\mu}\}. \end{aligned}$$

Now choose λ with $\lambda \geq \eta(c')$. Since $\lambda \geq 0$, the vector $\lambda c'$ remains ordered. Hence, by Theorem 2,

$$(3.7) \quad \lambda W_{c'}(A) = W_{\lambda c'}(A) = \{\text{tr}(HA) : H \in \mathfrak{H}_{\lambda c'}\}.$$

From (3.6), (3.7) we see that in order to prove (3.3) it suffices to show that

$$(3.8) \quad H_\mu \subset H_{\lambda c}.$$

Thus, let H_0 be a matrix in H_μ . Then by (3.2), there exist elements $H_c \in H_c$ for all $c \in \mathfrak{N}$, such that

$$H_0 = \int_{\mathfrak{N}} H_c d\mu(c).$$

The matrices H_c satisfy Definition 2, and since μ is a nonnegative measure on \mathfrak{N} , it follows that for ℓ -tuples x_1, \dots, x_ℓ in Λ_K we have

$$(3.9) \quad \sum_{j=1}^{\ell} (H_0 x_j, x_j) = \int_{\mathfrak{N}} \sum_{j=1}^{\ell} (H_c x_j, x_j) d\mu(c) \leq \int_{\mathfrak{N}} (\gamma_1 + \dots + \gamma_\ell) d\mu(c); \quad \ell = 1, \dots, n,$$

with equality for $\ell = n$. Since $\sum \gamma_j = \sum \gamma'_j = 0$, the above equality for $\ell = n$ implies

$$(3.10a) \quad \sum_{j=1}^n (H_0 x_j, x_j) = 0 = \lambda \sum_{j=1}^n \gamma'_j.$$

For $1 \leq \ell < n$ we use the assumption $\lambda \geq \eta$ to obtain from (3.9) that

$$(3.10b) \quad \sum_{j=1}^{\ell} (H_0 x_j, x_j) \leq (\gamma'_1 + \dots + \gamma'_\ell) \int_{\mathfrak{N}} \frac{\gamma_1 + \dots + \gamma_\ell}{\gamma'_1 + \dots + \gamma'_\ell} d\mu(c) \leq \lambda (\gamma'_1 + \dots + \gamma'_\ell).$$

By Definition 2, the relations (3.10) mean that $H_0 \in H_{\lambda c}$. Hence, (3.8) holds, and consequently the inclusion in (3.3) follows.

For $\lambda \leq \zeta$ the situation is slightly different. Consider the vector $c'' \equiv (-\gamma'_n, \dots, -\gamma'_1)$. Since c' is ordered, c'' is too. Also, the condition $\lambda \leq \zeta(c')$ becomes

$$(3.11) \quad -\lambda \geq -\zeta(c') = -\min_{1 \leq \ell < n} \int_{\mathfrak{N}} \frac{\gamma_1 + \dots + \gamma_\ell}{\gamma'_1 + \dots + \gamma'_{n-\ell+1}} d\mu(c) = \max_{1 \leq \ell < n} \int_{\mathfrak{N}} \frac{\gamma_1 + \dots + \gamma_\ell}{-\gamma'_1 - \dots - \gamma'_{n-\ell+1}} d\mu(c) \\ = \eta(c'').$$

Hence, by the previous part of the proof, we have that

$$(3.12) \quad \int_0 W_c(A) d\mu(c) \subset -\lambda W_{c''}(A), \quad \forall A \in C_{n \times n}.$$

But $-\lambda c''$ is merely a reordering of $\lambda c'$. Thus, the set on the right of (3.12) satisfies

$$-\lambda W_{c''}(A) = W_{-\lambda c''}(A) = W_{\lambda c'}(A) = \lambda W_{c'}(A),$$

and we obtain (3.3).

To complete the proof we have to show that if $\zeta < \lambda < \eta$, then (3.3) does not hold for some $A \in C_{n \times n}$. First assume $0 \leq \lambda < \eta$. That is, for some ℓ , $1 \leq \ell < n$,

$$(3.13) \quad \lambda(\gamma_1' + \dots + \gamma_\ell') < \int_0 (\gamma_1 + \dots + \gamma_\ell) d\mu(c).$$

Consider the matrix $A_\ell = I_\ell \oplus O_{n-\ell}$. A simple computation shows that for an ordered vector c , the range $W_c(A_\ell)$ is a real interval with right end-point $\gamma_1 + \dots + \gamma_\ell$. Then, the left side of (3.3) represents a real interval with right end-point

$$\int_0 (\gamma_1 + \dots + \gamma_\ell) d\mu(c),$$

which, by (3.13), exceeds the right end-point $\lambda(\gamma_1' + \dots + \gamma_\ell')$ of $W_{\lambda c'}$.

Finally, if $\zeta(c') < \lambda < 0$, then (3.11) implies that $0 < -\lambda < \eta(c'')$ where $c'' = (-\gamma_n', \dots, -\gamma_1')$. Thus by the above example the inclusion

$$\int_0 W_c(A_\ell) d\mu(c) \subset -\lambda W_{c''}(A_\ell) = \lambda W_{c'}(A_\ell)$$

fails to hold, and the theorem follows.

We remember of course, that we restricted integration to the domain 0 for convenience only. Therefore, if so desired, $\mu(c)$ can be

extended to the domain C , and Theorem 3 remains valid.

If μ is concentrated at a finite number of vectors $c_1, \dots, c_m \in C$, then Theorem 3 characterizes all λ for which

$$\sum_{i=1}^m \mu(c_i) W_{c_i}(A) \subset \lambda W_c(A), \quad \forall A \in C_{n \times n}.$$

A result of this type is given in Theorem 1 of [2].

Of particular interest is the case where μ is concentrated at a single vector $c'' \in C$. That is,

$$\int_C W_c(A) d\mu(c) = W_{c''}(A),$$

and η, ζ of (3.13) are given now by

$$\eta(c') = \max_{1 \leq l < n} \frac{\gamma_1'' + \dots + \gamma_l''}{\gamma_1' + \dots + \gamma_l'}; \quad \zeta(c') = \min_{1 \leq l < n} \frac{\gamma_1'' + \dots + \gamma_l''}{\gamma_1' + \dots + \gamma_l'}.$$

Thus, from Theorem 3 we conclude,

COROLLARY. Let $c' \neq 0$ and c'' be ordered vectors with $\sum \gamma_j' = \sum \gamma_j'' = 0$.

Then

$$W_{c''}(A) \subset \lambda W_{c'}(A), \quad \forall A \in C_{n \times n}$$

if and only if $\lambda \geq \eta(c')$ or $\lambda \leq \zeta(c')$ where η, ζ are given in (3.14).

This result was proved differently in Theorem 8 of [3].
